Summary

limHaloPT is a modular numerical package, written in C, for computing the clustering and shot-noise contributions to the power spectrum of line intensity/temperature fluctuations using the halo-model framework. This package is the first publicly available code, which combines the one-loop prediction of the halo power spectrum and the halo-model framework to model the power spectrum of emission lines originating from star-forming galaxies. Furthermore, the code includes routines to compute the stochastic contributions to line power spectrum beyond the Poisson approximation. Several utility functions, e.g., for computing the theoretical halo mass functions, halo biases, one-loop halo power spectrum, are provided in the package, which can be used in contexts other than LIM. This code is released together with a scientific publication ([Moradinezhad Dizgah et al., 2021](#)), in which details of the implemented model and the comparison of model predictions against simulated intensity maps are presented. The current version of the code includes the rotational ladder of carbon monoxide, CO, and fine structure line of ionized carbon [CII], and the model of the power spectrum is limited to real space.

Scientific Context and Statement of Need

Line intensity mapping (LIM) is a novel technique to map the large-scale structure (LSS) of the Universe by measuring aggregate emission of the atomic and molecular emission lines from the unresolved sources ([Kovetz, 2017](#)). Measurements of spatial fluctuations and frequency of the line provide a 3-dimensional map of the LSS, whose statistical properties capture a significant amount of information about astrophysics and cosmology. To fully exploit this rich data, accurate theoretical models of the signal and efficient numerical codes for evaluating the models are crucial.

The modeling of the line signal is based on the halo-model framework and requires two main ingredients; modeling the relation between line luminosity and halo masses and modeling the relation between halo properties and the underlying dark matter distribution. Until now, the models used in the literature neglect the nonlinear effects in the latter relation and use the tree-level perturbation theory to relate the halo properties, and by extension line intensity properties, to the underlying dark matter distribution. As of numerical implementation, the only publicly available code to compute the line power spectrum, [HaloGen](#) ([Schaan & White, 2021](#)), is based on this simplified model.

The extended halo model of line intensity power spectrum implemented in limHaloPT combines the predictions of EFTofLSS in Eulerian space for halo power spectrum ([Baumann et](#)

41 [al., 2012; Carrasco et al., 2012](#)) with the standard halo model ([Cooray & Sheth, 2002; Seljak,](#)
42 [2000](#)) to account for nonlinear evolution of matter fluctuations and the nonlinear biasing rela-
43 tion between line intensity fluctuations and the underlying dark matter distribution in 2-halo
44 term. Furthermore, the model includes the effect of large bulk velocities i.e., the Infrared
45 Resummation ([Blas et al., 2016; Senatore & Zaldarriaga, 2015](#)) in the 2-halo term. The
46 deviations from Poisson shot noise on large scales are also computed within the halo model
47 ([Ginzburg et al., 2017](#)).

48 Recently, there has been a shift in the cosmology community in publicly releasing the packages
49 developed by various groups to facilitate the follow-up research by the wider community,
50 without the need of each research group to replicate the numerical tools previously developed
51 by other groups. Great examples of this approach are [CLASS](#) Boltzman code ([Blas et al.,](#)
52 [2011](#)), and [nbodykit](#) ([Hand et al., 2018](#)) toolkit for analysis of the LSS data from Nbody
53 simulations and from galaxy surveys. In LIM, [limHaloPT](#) is the first package that includes
54 detailed modeling of the line power spectrum. The modular structure of the package facilitates
55 future extensions of the code to other LIM statistics, such as bispectrum, as well embedding
56 this code in a full likelihood analysis pipeline such as [CosmoSIS](#) ([Zuntz et al., 2015](#)).

57 Dependencies

58 The ‘[limHaloPT](#)’ package calls various functions from [CLASS](#) Boltzman solver, including the
59 matter power spectrum and transfer functions, growth factor, etc. Furthermore, the loop
60 calculations are performed with direct numerical integration, using routines of [CUBA](#) and
61 [Cubature](#) libraries for C. The code also uses several functions of [GSL](#) scientific library.

62 Future Extensions

63 Future releases will provide additional modules, for example, to include observational effects
64 such as redshift-space distortions and the Alcock-Paczynski effect. Furthermore, we plan
65 to extend this code to include modeling of other emission lines originating from star-forming
66 galaxies, cross-correlations between different emission lines, and the bispectrum of line intensity
67 fluctuations.

68 Acknowledgements

69 The research of A.M.D. is supported by the SNSF project “The Non-Gaussian Universe and
70 Cosmological Symmetries,” project number:200020-178787. A.M.D., further acknowledges
71 partial funding from Tomalla Foundation for Research in Gravity.
